37

Abstract: 38

Sensorineural hearing loss is an extremely serious disease of the hearing system, and leads to complete deafness until the manufacturing of a replacement of the auditory nerve; which is the implantable 39
40

auditory helix device. Computer simulation of the helix and its operation allow 41

researchers and students alike to be able to study the various parameters that 42

influence the performance of the helix. MATLAB environment is used, which 43

allows the possibility of presenting a research and training platform. It has become 44

feasible now to apply various audio signals and speech situation to the input of the 45

helix, and knowing the mechanism of processing it, and then hearing it as the 46

patient receives it. This simulation system is intended to be a comprehensive 47

simulation program to allow investigating the various implanted cochlear systems 48

available on the market or even those systems that not available on the market yet. 49

It allows the of various types and magnitudes of the noise and interference at the 50

input of the helix and at its different stages. Utilizing all the capabilities which 51

MATLAB provides to improve sound processing or even design several models of 52

signal processing techniques, comparing them and choosing the most appropriate ones is also provided. 53

It also feasible to conduct and test the simulation. 54

In this research, we proposed a simulation model using the MATLAB environment. This model not 55

only simulates the various parts of the helix, but allows the introduction of different audio signals and 56

speech situations combined with all kinds of noise that might accompany the speech. provides us with a 57

simulation of the device's operation by entering an audio signal and then processing it with an 58

explanation of all the stages that the signal goes through. This proposed model allows us to hear the 59

audio signal that the patient receives, after which it is decided whether or not to make adjustments to 60

the model. 61

Keywords: cochlear implant surgery, climatic effects on helix, residual hearing after cochlear implant 62

surgery. 63

1. Introduction:

65
66 The combination of engineering and
67 medical sciences has led to finding
68 solutions to many complex health problems,
69 the most prominent of which are hearing
70 disorders that hinder a person's
71 communication with his surroundings.
72 Traditional medical hearing aids were a
73 treatment for conductive hearing loss
74 resulting from a defect in the outer or
75 middle ear, which impedes the transmission
76 of mechanical vibrations to the inner ear.
77 The work of hearing aids is limited to
78 amplifying sounds. As for sensorineural
79 hearing loss, which results from a lack of
80 stimulation and auditory nerve as a result of
81 damage to the hair cells in the ear. The inner
82 ear led to the idea of electrical stimulation
83 of the remaining healthy nerve cells
84 directly, but speech was not initially
85 understood by the patient. With the
86 development of techniques used for
87 auditory stimulation, a patient became able
88 to understand speech well, and the efforts of
89 researchers in sciences such as medicine,
90 sound, and signal processing were fruitful
91 with the emergence of a prosthetic device
92 that contributes to restore hearing to a deaf
93 person. It is the implanted hearing helix
94 device, which stimulates healthy nerve
95 cells. The biggest challenge for the success
96 of the implanted helix device was how to
97 stimulate the neurons appropriately to
98 deliver useful information about the sound
99 signal that can be perceived by the brain.

100 2. If we want to provide a simple definition of
101 the implanted auditory helix, it is a device
102 that extracts the sound signal from the
103 external environment via a microphone and
104 analyzes it using an audio analyzer or so-
105 called speech processor to encode the
106 information contained in the speech signal
107 and convert it into electrical impulses to
108 stimulate the auditory nerve, and thus it
109 simulates in its work normal helix action in
110 the inner ear.

3. Literature Review:

111
112 In 1995, Shannon performed a simulation that
113 focused on the amount of spectral and temporal
114 information required to perceive speech. This
115 simulation divided the signal into four
116 frequency bands, and the envelope in each band
117 was extracted using a half-wave rectifier and a
118 low-pass filter (various cut-off frequencies were
119 applied and tested). The envelopes were
120 organized and filtered. Noise using the same
121 bandpass filters that were used in the analysis
122 phase of processing and all bands were
123 collected and presented over the speakers. The
124 stimulus included medial consonants (a
125 consonant between two vowels), vowels and
126 simple sentences, after training on all sounds,
127 eight listeners were asked to discriminate each
128 stimulus. Differences in low-pass cut-off
129 frequencies did not affect significant
130 performance differences. Designed to record
131 high speech perception (90% correct word
132 recognition), this perception can be achieved
133 using three analysis channels.^[3] In 1997,
134 Dorman performed a similar simulation, but he
135 researched using sine tones in addition to band-
136 limited noise, and the number of channels
137 varied between 2-9. When the number of
138 analysis channels increases, recording for
139 understanding vowels is approximately reached
140 at eight channels, while for understanding
141 sentences, five channels are reached Enough.^[3]
142 In 1999, Loiseau used a simulation to examine
143 the number of channels needed to understand
144 speech with multiple speakers. The stimulus
145 included phonetically rich sentences. Five
146 channels were needed to achieve 90% correct
147 recording. On the other hand, the results were
148 similar using eight channels. This simulation
149 included situational information not included in
150 the Treatment of transplanted auditory
151 helixes.^[3] In 2000, Weiss completed the most
152 detailed simulation in which he simulated not
153 only the signal processing of the auditory helix
154 implant but also some of the perceptual
155 limitations associated with hearing impairment.
156 His simulation was used to evaluate people's
157 results on speech comprehension tests, and the

158	results were similar to those performed on	204	these changes in climatic parameters. The
159	listeners with auditory helix implants. ^[3] In	205	simulation setup for the cochlear implant was

202	simulation was prepared, which provides	248	Receive signals from the speech processor
203	insights into the behavior of the signal under		and converts them into electrical impulses.

- 249 9. **4- Electrode array:** It is a group of
 250 electrodes that collect impulses from the
 251 stimulator and send them to different areas
 252 of the hearing nerve. [8]
 253 10. The figure below shows the main
 254 components of a cochlear implant:

255 11.
 256 *Figure(1) Parts of the cochlea. [8]*

257 **12.How cochlear implants work:**

- 258 13. The primary goal of a cochlear implant is to
 259 safely use electrical stimulation to provide
 260 or restore functional hearing. Figure 5-3
 261 graphically shows a typical modern
 262 cochlear implant system. The external
 263 behind-the-ear processor with a hook and
 264 battery pack (2) uses a microphone to
 265 capture sound, convert it into a digital
 266 signal, process the digital signal, encode it
 267 (encrypt it) into a radio frequency (RF)
 268 signal and send it to the antenna inside the
 269 headpiece (3). The headpiece is then
 270 installed in Placed by a magnet attracted to
 271 an internal receiver (4) placed under the
 272 skin behind the ear, the hermetically sealed
 273 stimulator (5) contains active electronic
 274 circuits that derive energy from the radio
 275 frequency signal, it decodes the signal,
 276 converts it into electrical currents, and
 277 sends it along wires (6) interconnected in
 278 the cochlea. The electrodes (7) at the end of
 279 the wire stimulate the auditory nerve (8),
 280 which is connected to the central nervous
 281 system. It must be noted that these
 282 electrodes are activated based on
 283 frequencies The audio signal, those in
 284 the base area are excited with high
 285 frequencies (non-vocal signal), while the
 286 electrodes in the apex area are excited with
 287 low frequencies (vocal signal), and then the

electrical impulses are interpreted as sound.
 The number of healthy nerve fibers and
 their rate of excitation affect the loudness
 and loudness of the sound. The greater the
 number, the louder the sound, and vice
 versa, The loudness of the sound can be
 controlled by different amplitudes of the
 excitation current, so we can say that the
 implanted auditory auditory helix device
 transmits information about the loudness of
 the sound, which is indicated by the
 amplitude of the excitation current, and
 information about the frequency of the
 audio signal, which is indicated by the
 location of the electrodes.[4]

14.
Figure (2) How cochlear implants work. [4]

Figure (3) shows a box diagram showing the mechanism of operation of the implanted auditory helix hearing device, which we explained earlier.

Figure (3) is a box diagram showing the mechanism of operation of the cochlear implanted hearing device. [4]

15. **Multi-channel cochlear implant:** A multi-channel cochlear implant was developed rather than a single channel because electrophysiological research has shown that single-channel stimulation

313
 314
 315
 316
 317

318 cannot reproduce the high speech
 319 frequencies essential for speech
 320 understanding. The first commercial multi-
 321 channel cochlear implant was tested on a
 322 human participant in 1982, setting off the
 323 path of hearing implant innovation
 324 worldwide, with the US Food and Drug
 325 Administration (FDA) approving Cochlear
 326 Limited's Cochlear Nucleus 22 implant
 327 system (for use in adults). Those suffering
 328 from profound sensorineural hearing loss in
 329 1985 AD. [2]

330 **16. Practical application and its**
 331 **results:**

332 17. Simulating an implanted auditory helix is a
 333 software application that allows us to
 334 simulate how sound is received by a person
 335 undergoing a auditory helix implant. One of
 336 the functions of this application is to read
 337 an audio file in waveform or record an
 338 audio signal using the computer's
 339 microphone input. It is possible to configure
 340 the elements used for the simulation and
 341 simulate many in some cases, in addition,
 342 we can obtain a new audio signal from an
 343 original signal (a saved audio file or audio
 344 recording), This new signal is synthesized
 345 according to the selected simulation
 346 elements, and represents how the original
 347 auditory signal would be received by the
 348 patient. Conducting this simulation process
 349 ultimately allows us to obtain the best
 350 possible system for the implanted auditory
 351 helix after studying all cases and taking into
 352 account all influencing factors. We have
 353 studied the model applied within the
 354 MATLAB environment, which is prepared
 355 to simulate a 16-channel helix device,
 356 explaining the mechanism adopted in this
 357 simulation and the elements used.

358 **18. Cochlear implant model:**

359 19.

Figure(2) Simulation model of a cochlear implant.

360 20. The model consists of the following basic
 361 blocks:

- 362 21. 1- Input source block.
- 363 22. 2- Filter Bank (Signal Processing).
- 364 23. 3- Denoise block.
- 365 24. 4- Pulse Generator block.

366 **25. Input source block:**

367 26. The task of this block is to generate the
 368 audio signal that is considered an input
 369 signal for the implanted auditory helix's
 370 auditory device.

371 27. **To determine the type of audio**

372 **source:** The type of signal used here is
 373 Chrip, which means the audio signal whose
 374 frequencies increase little by little.
 375 Microphone signal. We can use other types,
 376 such as the speech signal, and one of the
 377 options may be to choose a sound signal
 378 (Y) to be read from the workspace (Signal
 379 from the workspace), but we only relied on
 380 the Chrip signal in this model. This is
 381 shown in Figure (5).

382 28.

Figure (5) Input block.

383 29. **Adding noise to the generated audio**

384 **signal:** This is done by adding a little noise
 385 to the input signal using Random Source,
 386 which is a random intermittent signal whose
 387 amplitude is between (+0.1_-0.1), to take
 388 into account the noise that will be
 389 associated with the signal received from the
 390 surrounding environment in the actual
 391 cochlear implant device.

392 30. The input signal is as shown in Figure (6).

393 394

Figure (6): Input signal format.

395
 396

Data processing methods adopted in the model: Filters block (signal processing): This block is similar in its work to the work of the audio analyzer that we talked about previously, as it filters the incoming audio signal and analyzes it into a group of frequency bands. In the studied model we have 16 frequency bands, as the auditory helix device. The one simulated is 16 channels. The filters used in this block are digital filters. The block of filters that process and we note from the model in Figure (4), consists of:

31. Cascade Multi-rate Multi-Stage FIR Filter Bank: which contains within it the FIR finite impulse response filter and the Rectifier, as shown in Figure (7)

Block of filters in the model. Figure(7)

413
 414

32. We divided the **FIR** filter into Two-Channel Analysis, shown in Figure (8), which distributes the signal into two parts: a Low Pass Filter and a High Pass Filter, which pass high and low frequencies. These filters are of the sixth order due to the presence of six coefficients to each their own.

421

Figure (8) FIR filter design.

33.

34. As for the filters, Filter1, Filter2, Filter3, and Filter4, they are filters that contain bandpass filters that work to pass frequencies between two specific values. The four filters differ from each other in the gain factor values only. Figure (9) shows the internal layout of the Filter1 block, which includes a gain factor of 2.

The internal layout of the Filter1 block, which includes a gain factor of 2. (Figure(9))

 425
 426
 427
 428
 429
 430
 431
 432
 433
 434

35. **Rectifier:** It is a wave rectifier, which we use to obtain a signal in one positive direction, for example, through absolute value (Abs), and then we combine the signal using Matrix Concatenate.

Internal design of the Rectifier. Figure(10)

36.

37. Figure (11) shows the shape of the signal after it exits the filtering unit.

440
 441
 442
 443

444 38. *The shape of the signal after it exits the filtering unit*
 445 *Figure (11)*
 446

447 **39.Noise removal block:**

448 40. The task of this block is to reduce noise, or
 449 rather to remove signals with low
 450 amplitudes, and to pass only signals whose
 451 amplitude in absolute terms exceeds the
 452 values at both ends of the dead zone. The
 453 signals in each of these channels pass
 454 through a different dead zone when the
 455 Denoise option is activated.

456 41. *Noise removal block Figure(12)*
 457

458 42. Figure (13) shows the shape of the signal
 459 after it exits the noise removal block.

461 44. *The shape of the signal after it exits the noise removal*
 462 *block. Figure (13)*
 463

464 **46.Electrical pulse generation**
 465 **block:**

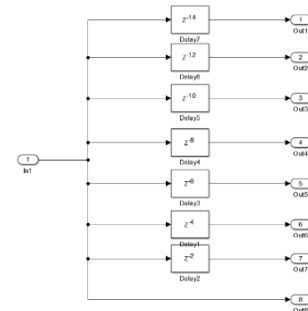

466 47. The task of this block is to generate
 467 asynchronous electrical pulses that will alert
 468 the different areas of the auditory helix and

469 modify the signals received from the
 470 various channels according to these pulses.
 471 It consists of two blocks, as shown in
 472 Figure (14):
 473 48. Interleaved Sampling Pulse Generator block
 474 49. Continuous Interleaved Sampling (CIS)
 475 block

476 50. *Figure(14) Pulse generation block.*
 477

478 51. The first block generates electrical pulses
 479 on 16 channels, and the pulse in each
 480 channel lags behind the channel that
 481 precedes it by z-x, and the value of x is
 482 what determines the number of samples that
 483 will be kept in each Delay, and here it is by
 484 two cycles, that is, asynchronously. We
 485 notice the presence of two Subsystem
 486 blocks, each of which contains 8 blocks.
 487 Delay, as shown in Figures (15) and (16).

488 53. *The first subsystem block. Figure (15)*
 489

490 55. *The second subsystem block. Figure (16)*
 491

56. *The second subsystem block. Figure (16)*

492 57. As for the second block shown in Figure
 493 (17), which represents one of the techniques
 494 adopted in multi-channel audio auditory
 495 helix devices, which is CIS, it works to
 496 modify the signals of the 16 channels
 497 coming from the filter block by multiplying
 498 the signals of each of them with the signals
 499 coming from the pulse generator so that we
 500 get a result for each sample. Two pulses,
 501 one of which has a positive amplitude and
 502 the other has a negative amplitude. This
 503 amplitude is equal to the amplitude of the
 504 sample corresponding to this pulse and
 505 coming from the filter block. We notice in
 506 the figure the Rate Transition element,
 507 which works to harmonize the blocks, each
 508 of which operates at a different cutting
 509 frequency.

510 58.

511 59. Figure (17) The second block of the pulse generator.

512 60. The shape of the signal after it exits the
 513 pulse generation block is as follows

514 61.

515 62.

516 63. Figure(18) The shape of the signal after it exits the
 517 pulse generation block.

518 64. **IIR filter:** This is similar in operation to
 519 the FIR filter but is similar in design
 520 according to Figure (19), that is, it returns
 521 the signal to a form that we can hear and
 522 see.

523 65.

66. Figure (19) IIR filter structure.

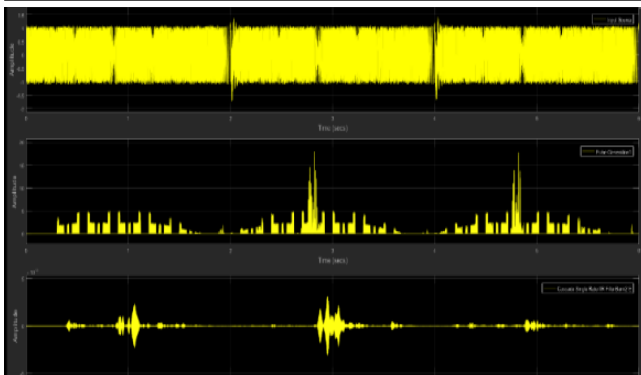

525 67. Thus, the simulation of the work of the
 526 implanted auditory auditory helix has been
 527 completed, but the MATLAB program
 528 provides us with the possibility of
 529 regenerating the speech signal in one of two
 530 ways: sequential or parallel. It is possible to
 531 regenerate it by re-filtering the signals
 532 multiplied by the resulting (modified)
 533 electrical pulses using infinite impulse
 534 response filters. Which we talked about
 535 previously, and then the filtering products
 536 are collected, and here the signal is
 537 generated serially from the different
 538 channels or the non-multiplied signals are
 539 re-filtered with electrical pulses
 540 (unmodulated), then the filtering products
 541 are collected, and here the audio signal is
 542 generated from the different channels in
 543 parallel, and all of that is done. Through the
 544 block of regeneration of the speech signal
 545 from the generated impulses.

546 68. x generation block. The list represents the output.

547

548 69. Results and Discussion:

549 Figure (20) shows a comparison between three
 550 signals. The first signal is the input signal that was
 551 entered into the system. The second signal
 552 represents the shape of the signal after it exits the
 553 pulse generation block. The list represents the
 554 output of the last stage after filtering, i.e. Expresses
 555 the final signal.

556
 557 Figure (20) comparison between three signals. The first signal
 558 represents the input signal that was entered into the system. The
 559 second signal represents the shape of the signal after it exits the
 560 pulse generation block. The list represents the output.

561 **Conclusion:**

562 Further investigation is necessary to be conducted
 563 and the system tested to come up with a robust
 564 platform and investigating two important signal-
 565 processing technologies, namely CIS and SPEAK,
 566 and developing more algorithms that enable to
 567 reduce noise better. By identifying the factors that
 568 cause differences the performance among patients,
 569 it can lead to developing signal-processing
 570 techniques in a way that matches the requirements
 571 of each patient.
