### Abstract:

To guarantee continuous operation of medical equipment, it is essential to use dependable and uninterrupted power sources. This paper proposes a portable power supply system that is based on rechargeable batteries and a PV system to ensure the operation of EMS-apparatus. The photovoltaic panel of the presented system uses semiconductor silicon converters with nano-modified receiving surfaces.

Keywords: Photovoltaic panel, Nanomodified solar cell surface, EMS-apparatus, Rechargeable batteries, Solar generation system.

## 43 1. Introduction:

44 EMS-technologies are used to treat patients with  
45 muscular atrophy, musculoskeletal diseases, and  
46 injuries to joints and limbs. This contributes to  
47 increased treatment efficiency and patient recovery.  
48 Ensuring the quality operation of medical equipment  
49 is a crucial task for medical institutions,  
50 rehabilitation centres, temporary hospitals, and field  
51 sanitary facilities. This can be achieved through the  
52 use of energy-saving technologies and independent  
53 energy sources, particularly for EMS devices. It is  
54 important to maintain uninterrupted operation of  
55 medical equipment. The work proposes various types  
56 of power supplies for non-patient care settings that  
57 are independent of central power lines. These devices  
58 use renewable energy sources, specifically solar  
59 batteries with highly efficient photoconverters and  
60 energy storage systems. Therefore, many studies  
61 focus on solar energy harvesting for PV self-powered  
62 applications (Fig. 1)[1, 2]. These power systems do  
63 not replace the main generating capacity of medical  
64 institutions and do not complicate their operation.  
65 Instead, they effectively assist the operation of  
66 medical equipment in non-stationary conditions.  
67 Additionally, these systems do not emit harmful  
68 substances and contribute to improving the  
69 environment. Therefore, the proposed systems can be  
70 confidently referred to as reliable sources of power  
71 supply for low-power medical equipment. The use of  
72 backup power supply and energy storage systems  
73 based on photovoltaic energy sources in health care  
74 facilities can significantly reduce the negative effects  
75 of conventional fossil fuels. These systems can be  
76 either thermal or electrical energy storage systems or  
77 additional generating units. These systems can be  
78 installed both in medical centres and mobile  
79 hospitals and work together with stationary power  
80 plants, which allows them to be effectively used as  
81 alternative energy sources [3]. Of all types and kinds  
82 of low-power backup power supply systems,  
83 photovoltaic systems with energy storage fulfill the  
84 necessary requirements [4]. EMS-technologies are  
85 used to treat patients with muscular atrophy,  
86 musculoskeletal diseases, and injuries to joints and  
87 limbs. This contributes to increased treatment  
88 efficiency and patient recovery. Ensuring the quality  
89 operation of medical equipment is a crucial task for

90 medical institutions, rehabilitation centres,  
91 temporary hospitals, and field sanitary facilities. This  
92 can be achieved through the use of energy-saving  
93 technologies and independent energy sources,  
94 particularly for EMS devices. It is important to  
95 maintain uninterrupted operation of medical  
96 equipment. The work proposes various types of  
97 power supplies for non-patient care settings that are  
98 independent of central power lines. These devices  
99 use renewable energy sources, specifically solar  
100 batteries with highly efficient photoconverters and  
101 energy storage systems. Therefore, many studies  
102 focus on solar energy harvesting for PV self-powered  
103 applications (Fig. 1)[1, 2]. These power systems do  
104 not replace the main generating capacity of medical  
105 institutions and do not complicate their operation.  
106 Instead, they effectively assist the operation of  
107 medical equipment in non-stationary conditions.  
108 Additionally, these systems do not emit harmful  
109 substances and contribute to improving the  
110 environment. Therefore, the proposed systems can be  
111 confidently referred to as reliable sources of power  
112 supply for low-power medical equipment. The use of  
113 backup power supply and energy storage systems  
114 based on photovoltaic energy sources in health care  
115 facilities can significantly reduce the negative effects  
116 of conventional fossil fuels. These systems can be  
117 either thermal or electrical energy storage systems or  
118 additional generating units. These systems can be  
119 installed both in medical centres and mobile  
120 hospitals and work together with stationary power  
121 plants, which allows them to be effectively used as  
122 alternative energy sources [3]. Of all types and kinds  
123 of low-power backup power supply systems,  
124 photovoltaic systems with energy storage fulfill the  
125 necessary requirements [4].

## 2. Material and Methods:

When operating energy complexes to supply medical institutions, it is necessary to have some reserve power at all times in order to reduce the negative impact of power shortages, as well as in the event of frequent disconnections of centralized power supplies or the absence of a common power grid. The necessary energy is stored in batteries or other back-up storage devices. The required energy can be obtained either from the general grid or by using generating solar power installations [5]. A solar charging station based on photovoltaic converters and Batteries is an effective solution to provide electricity to hospitals and treatment infrastructure. The proposed standby power supply system's consist of a hybrid power system equipped with various power generators: low-power photovoltaic panels, compact solar cells, portable generators in containers, as well as a system of electricity storage and distribution [6]. The main advantages of such installations are their mobility and compactness. The aim of this work was to ensure the quality operation of medical equipment by utilizing high-efficiency solar cells and energy storage devices. This would enable uninterrupted operation of various low-power medical equipment and EMS-apparatuses. To achieve this goal, high-efficiency silicon

155 photoconverters with nanomodified surfaces and 156 battery for uninterrupted power supply. The systems 157 proposed in this work are designed for continuous 158 use in non-patient environments and can be relocated 159 outside medical facilities. To achieve this, 160 photoconverters with enhanced energy performance 161 were selected [7]. The aim of this study was to 162 develop an energy-efficient solar panel for charging, 163 based on a photovoltaic converter with a 164 nanomodified receiving surface [8]. This panel could 165 be used to ensure uninterrupted operation of the EMS 166 device shown in Fig. 2. The electrical performance of 167 photoconverters, battery capacity, and the number of 168 solar cells are the main technical parameters that 169 determine the quantitative, qualitative, and cost 170 characteristics of the products. In this study, a 300 W 171 photovoltaic panel was used to charge the battery. 172 The panel consisted of nanomodified photovoltaic 173 cells, a charge-discharge controller, and other 174 auxiliary equipment. The silicon nanomodified cells 175 presented in this study were processed in the 176 laboratory of spark plasma sintering at MSTU 177 'Stankin' in Moscow. They exhibit high performance 178 characteristics, including increased efficiency, 179 protection against overheating, and increased 180 hardness.

181

182 Figure 2 - External view of EMS-apparatus (Electric 183 Mio Stimulation)

184 The devices used enable compliance with all design  
185 requirements, including technological, reliability,  
186 operational, maintenance, repair, storage, packaging,  
187 labelling, and transportation requirements for  
188 medical equipment. The laboratory of Spark Plasma  
189 Sintering at MSTU 'Stankin' has developed elements  
190 with improved performance characteristics.  
191 Specifically, these elements exhibit greater heat  
192 resistance, significantly higher impact resistance  
193 compared to conventional silicon elements, and a  
194 20% increase in efficiency value compared to  
195 unmodified elements. Additionally, these elements  
196 are more resistant to transport and experience less  
197 degradation during operation.

### 198 3. Results and Discussion:

199 To provide stable power generation and reliability of  
200 the charging system, a combined photovoltaic system  
201 with energy storage was used. As previously stated in  
202 this work, field tests were conducted on the 300 W  
203 PV systems, consisting of photovoltaic panels (each  
204 with a capacity of 300 W), a 40 Ah battery, inverters,  
205 and other equipment (Fig. 3). This system can be  
206 connected to the grid and operate autonomously. The  
207 compact size of the system enables it to be easily  
208 transported and used in the field. Additionally, the  
209 high-quality photovoltaic converters greatly enhance  
210 work efficiency.

211  
212 Figure 3 - Basic equipment for the backup power  
213 supply system of medical equipment and EMS-  
214 apparatus

215 During the research process, we conducted full-scale  
216 experimental studies on the operation of the system.  
217 To increase the efficiency of solar plant operation  
218 and reduce electricity losses, it is essential to  
219 optimize the use of both main and auxiliary  
220 equipment [5]. Therefore, we conducted  
221 experimental studies on the plant's operation. Figure  
222 4 displays the power characteristics of a single

223 module in a 300 W solar plant during summer  
224 months under varying illumination.

225  
226 Figure 4 - Power characteristics of a 300 W photovoltaic  
227 panel.

228 For the operation of the backup system as an energy  
229 storage device the accumulator batteries were used.  
230 Through experimentation, we obtained data on the  
231 charging capacity of the battery in relation to  
232 charging time (refer to Fig. 5). The graph shows that  
233 the battery reaches 15% of its nominal capacity after  
234 1 hour of charging. It takes 8-14 hours to charge the  
235 battery from 30% to 98% of its capacity. For  
236 qualitative analysis of energy storage, it is necessary  
237 to check the parameters of the charging current,  
238 which corresponds to the capacity divided by 10.6,  
239 time required to charge up to 98% is up to 10 hours.

240  
241 Figure 5 - The dependence of the relative charge capacity  
242 on time.

243 To determine the sufficient percentage of charge, it is  
244 necessary to carry out experimental testing of the  
245 dependence of the charging current on the solar radiation  
246 flux falling on the working surface of the panel. In this  
247 case, the angular coefficient was assumed to be about 0.8.  
248 I.e., the irradiance is about 800 W/m<sup>2</sup>, the charging current  
249 characteristic is shown in Fig. 6.

250

251 Figure 6 - The dependence of the charge current on the  
252 irradiance

253 These studies are very significant for further calculations  
254 of charging and operation of the battery station in  
255 combination with photovoltaic modules used as  
256 uninterrupted power supplies for medical equipment. The  
257 use of the proposed systems makes it possible to provide  
258 autonomous power supply both for own needs and for  
259 stationary objects. The use of photovoltaic units as  
260 generation systems provides reliable operation of medical  
261 equipment in the absence of central power supply. The  
262 proposed backup power supply systems do not replace the  
263 main generating capacities and do not complicate their  
264 operation, while they effectively assist their operation.  
265 Also, these systems do not produce harmful emissions and  
266 improve the environment.

267 Conclusions: The research results suggest that an system  
268 for powering medical equipment has been proposed, using  
269 photovoltaic systems with energy storage when working  
270 together with the centralised grid. The batteries can be  
271 charged either from solar energy or from the general grid.  
272 The use of independent power supply allows the medical  
273 equipment to be used in the field. This work proposes  
274 high-quality solar cells with increased efficiency and  
275 quality characteristics such as protection against  
276 degradation, utilization of the diffused solar radiation flux,  
277 and prevention of overheating of the working surface.

278 The article proposes a methodology for using different  
279 sources to accumulate and generate electric energy,  
280 specifically focusing on the use of backup and  
281 uninterruptible power sources for medical equipment. The  
282 use of renewable energy sources to power medical  
283 equipment is an important task in many regions, as it  
284 improves the environment and reduces dependence on  
285 traditional fossil fuels.
